Alprazolam was introduced in under the brand name Xanax, and is one of the most widely-abused prescription drugs, according to a study by the Substance Abuse and Mental Health Services Administration. Proving that a person is impaired by alprazolam is different than establishing intoxication from alcohol, Harper said. Last year, alprazolam was found in 29 percent of DUI cases, compared to 23 percent for marijuana. Harper said controlled driving tests can't necessarily be compared to typical driving performance. But the drug can affect driving ability even in those who are taking it as prescribed, and most doctors advise patients to avoid driving until they know how they are affected by the drug. Harper said he became the first toxicologist trained as a drug recognition expert during a recent three-week session that produced 10 new experts. The same drug appeared in the toxicology report for Caren Gayle Rush, who was convicted last year for manslaughter in a crash that killed a former high school softball star. And subjects who aren't used to taking alprazolam would show greater effects of the drugs than those who have been on them for an extended amount of time. Researchers are just beginning to gather similar data for marijuana, but there are no equivalent studies for other drugs. Although they can improve the symptoms of anxiety, benzodiazepines do nothing to address the root cause of the disorder, Hendricks said. In controlled driving tests, subjects who have received 1 milligram of alprazolam showed increased weaving, and several driving tests had to be stopped because subjects became too drowsy to continue. Since doctors have already begun to cut back on alprazolam prescriptions, Hendricks said he does not expect the problem of abuse to grow in coming years. Those studies initially set the limit for impairment at. The percentage of DUI cases caused by alprazolam has held steady for the past three years, according to the data. The data did not include car crashes, but Curt Harper, toxicology discipline chief for the Alabama Department of Forensic Science, said he believed those figures would be similar. When Harper testifies in court, he often uses data that shows that the level of the drug in a driver's system is much higher than therapeutic levels. It might have been sooner if he had alcohol in his system.
